OVER THE PERIOD MARCH 13-20, 1989, A SERIES OF T-SCAN THICKNESS MAPPING SURVEYS WERE CONDUCTED TO ESTABLISH A CORROSION MONITORING BASELINE OF STORAGE TANK #2. CONTINUATION OF THE PROGRAM IN OCTOBER, 1989, INCLUDED RE-SCANNING OF THE TANK #2 BASELINE AREAS, PLUS ESTABLISHING BASELINE DATA ON TANKS #1 AND #3. THIS REPORT DESCRIBES AND DOCUMENTS THE SCANNING DONE DURING THE OCTOBER SURVEY.

THE THREE STORAGE TANKS WERE SUBJECTED TO EIGHT VERTICAL AUTOMATED THICKNESS MAPPING EXAMINATIONS USING THE P-SCAN EQUIPMENT. TWO HORIZONTAL SCANS WERE ALSO PERFORMED FOR EACH TANK. THE AREAS SCANNED REVEALED ONLY SLIGHT VARIATIONS OF WALL THICKNESS, ALTHOUGH A SMALL LOCALIZED AREA OF TANK #2 WAS FOUND TO HAVE EXPERIENCED A WALL LOSS OF 0.090 INCHES SINCE MARCH.

RADIOGRAPHIC SURVEYS WERE PERFORMED ON THE ATTACHMENT VALVES, V-1 THROUGH V-8. TWO VALVES ON TANK #2 WERE FOUND TO HAVE CORROSION.

REPORT OF T-SCAN EXAMINATION UTILIZING EXTREME
VALUE ANALYSIS

Tested By: Karl Van Scyoc Test Date: 25OCT89
 Patrick Burke

Prepared By: Karl Van Scyoc Date: 15NOV89

Approved By:  Date: 00DEC.'89

CLIENT: SIP Engineering/Shell Chemicals

Test Location: Rocky Mountain Arsenal, Denver, Colorado

Test Item: Basin F, Interim Storage Tank Numbers 1, 2, 3

Exam Surface: Original paint intact, girth welds ground flush at examination areas.

System : PSP-3 #205
Probe : Sigma, 4MHz Dual
Scanner: AWS-5S #002
I-CODE: EDGE contact, PEAK-EDGE Contact
Evaluation: PEAK-EDGE Contact

RESULT SUMMARY

Storage Tank Numbers 1, 2 and 3 were subjected to eight vertical automated thickness mapping examinations using the P-SCAN equipment. Additionally, two 10' long horizontal scans were performed for each tank. These scans served to establish a baseline for Tanks 1 and 3, and re-assess the existing baseline areas of Tank #2 (Ref. DNV Report C04489). The areas scanned on Tanks 1, 2, and 3, reveal only slight variations of wall thickness, although a small localized area of Tank #2 was found to have experienced a wall loss of 0.090 inches since the March 1989 baseline. This thinning prompted scanning of two additional horizontal scans to evaluate the extent of the thickness reduction.

Application of Extreme Value Analysis, EVA (a statistical technique used to calculate the maximum pit depth for the entire tank wall) predicted slight wall loss in Tanks 1 and 3, and predicted the presence of the Tank #2 thin area.

Radiographic surveys were performed on the attachment valves, V-1 through V-8. Two exposures (horizontal and vertical) were obtained for each valve. Tank #2, V-7 and V-8 were the only valves reported to have corrosion. A machine screw was found in Tank #1, V-5.

A full accounting of the surveys may be found in the following sections.

1.0 INTRODUCTION

Three storage tanks 70' diameter and 49' in height were placed in service in 1987 for interim storage of hazardous waste at the Rocky Mountain Arsenal. The tank walls were constructed of five steel plate courses ranging in nominal thickness from 0.75" to 0.95", thereby providing ample corrosion allowance. Each tank was fitted with a plastic liner which extended over the floor and against the wall. It was discovered that the liner in Tank #2 had developed perforations which allowed storage-product contact with the steel wall.

At the time of liner perforation, the rate of corrosion was not determined. As a complement to corrosion rate studies (which showed corrosion rates from 0.028" to 0.260" per year), an in-situ corrosion monitoring program was formulated.

Over the period of March 13 through March 20, 1989, DNV Industrial Services conducted a series of T-SCAN thickness mapping surveys to establish a corrosion monitoring baseline of Tank #2. Continuation of the program in October, 1989 included re-scanning of the Tank #2 baseline areas, plus establishing baseline data of Tank #1 and Tank #3.

This report describes and documents the scanning conducted during the October survey. Vessel referencing and scanning technique are addressed to ensure reproducibility in subsequent scanning sessions.

1.1 Previous Ultrasonic Baseline Data

Members of the DNV QAS group obtained pre-service baseline thickness data in May, 1988. Twelve sample areas were selected for each of the three tanks, with each sample area measuring 18 x 24 inches. Thickness measurements were taken within each sample area using a 3" grid, providing a total of 63 measurements for each sample area. Paint was removed at each measurement location. Full details of the DNV QAS baseline measurement project may be found in the QAS report number 88-1400-83-01. Excerpts of the QAS report that are relevant to this examination report are noted in the Discussion-section.

2.0 **EQUIPMENT**

The following equipment was used to conduct the T-SCAN surveys of Basin F Storage Tanks.

P-SCAN Processor	#205
Automatic Scanner AWS-5S	#002
DSC Block, Steel	#797021
Step Wedge, Steel	#88-5014
Couplant	Water/Water-antifreeze
Cables	RG-58, 25 meters
Search unit	Sigma, Dual Element, 4.0 MHz, SDC4-F8.5, s/n 7001-88008

All ultrasonic equipment has current calibration in accordance with DNV procedures.

3.0 PROJECT SCOPE

The goals of the October, 1989 scanning session were to execute all of the following tasks for each of the three tanks:

- a. Perform automated thickness mapping of a 12" wide vertical strip extending vertically from the wind girder to the primary floor. A vertical scan was to be performed approximately every 45 degrees, for a total of eight scan sequences.
- b. Perform automated thickness mapping of two 12" wide horizontal strips, each extending for 120" in length. The horizontal scans were confined to Course 5 and placed (1) between the transfer line flanges and (2) over the manway without the code plate.
- c. Apply a statistical extrapolation (known as Extreme Value Analysis, EVA) to the automated T-SCAN vertical surveys to predict the maximum pit depth.
- d. Obtain vertical and horizontal radiographic exposures of eight 1.5" diameter valves. Hence, for each tank, 16 exposures were required.

3.1 Additional Documentation of Tank #2

During evaluation of survey data, it was noted that a localized area of Tank #2 experienced a substantial change in wall profile. Consequently, DNV was requested to carry out two additional horizontal scans to assess the extent of wall loss.

PROJECT ORGANIZATION AND VESSEL REFERENCING

An arbitrary referencing scheme was established at the inspection site, which is illustrated in Figure 4.1 through Figure 4.6 and discussed below.

Course Numbering The wall courses are arbitrarily numbered as 1 through 5. The top course with the wind girder is Course 1, and the bottom course at the primary floor is Course 5.

Scan Sequence Nos. Scan sequences are designated by numbers extending from Scan 1 through Scan 8, with Scan 1 on the North side. Scan Sequence numbering continued counter-clockwise (looking from the top). Scan sequences were positioned whereby automated exams would intersect the pre-service grid measurement areas where practicable.

Nozzle Referencing Nozzles and manway designations are noted in Figures 4.1 through 4.3. Valves V-1 through V-8 were subjected to radiographic examination.

4.1 Scan Sequences and T-SCAN File Convention

Each image, or part, of a scanning sequence is identified with a filename (ITEM) which may be used to correlate the image with a uniquely identifiable portion of the scan area. The filename may be found at the lower right corner of each T-SCAN printout. Filenames for the surveys were defined as discussed below.

4.1.1 Vertical Scans

While a continuous vertical scan was accomplished at each of the eight scan locations, each vertical scan was divided into 5 scan sequences of approximate length 96 inches. (Figure 4.6). Additionally, each 96" long sequence is composed of 4 parts or images of dimension 12" x 24". The segmenting of image data is necessary for documentation and accurate referencing. The image files saved on 3.5" floppy diskettes follow the convention:

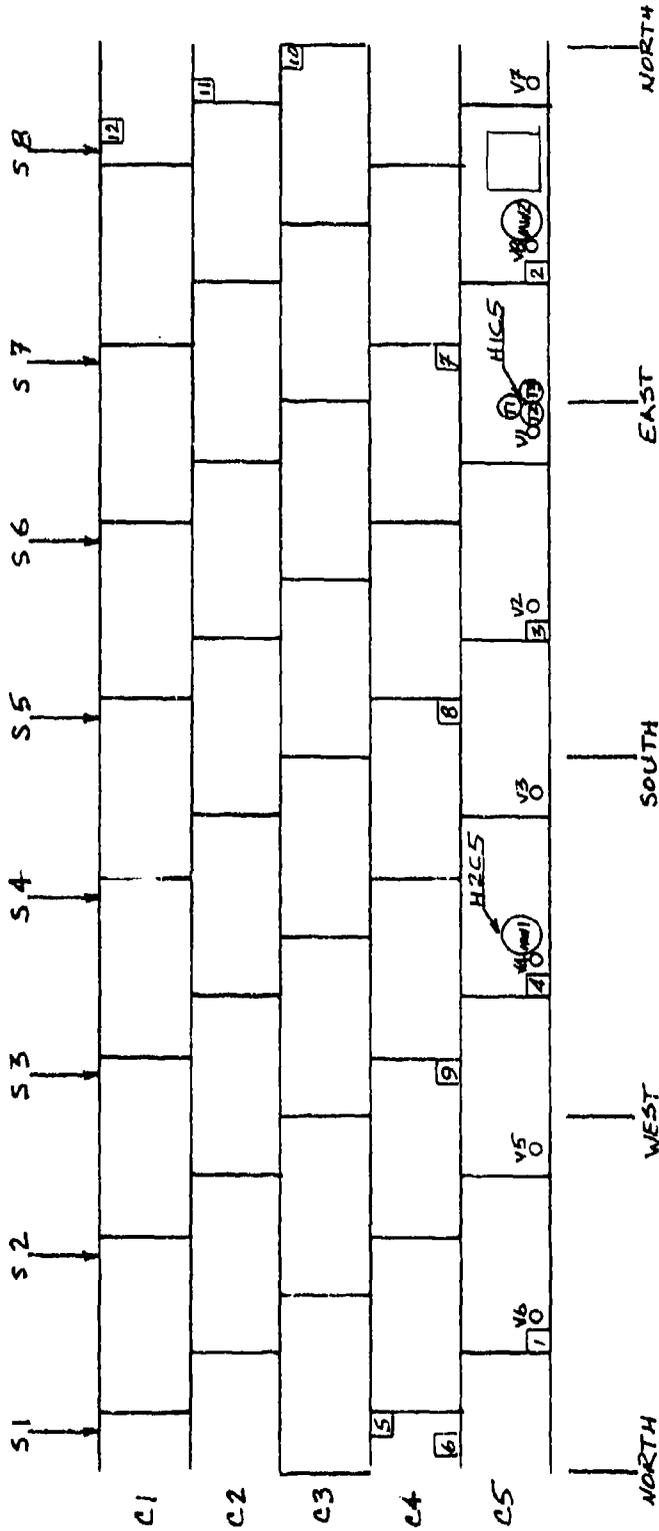

TKn-SsCc.p	where	TKn	Identifies the Tank Number, 'n'
		Ss	Identifies the vertical Scan number
		Cc	Identifies the Course number, 'c'
		.p	Denotes the part number

4.1.2 Horizontal Scans

All horizontal scans are 120" in length and reside in course 5. The horizontal scan file convention is similar to that of the vertical scans:

TKn-HhCc.p	where	TKn	Identifies the Tank Number, 'n'
		Hh	Identifies the Horizontal scan number, 'h'
		Cc	Identifies the Course number, 'c'
		.p	Denotes the part number.

Horizontal scan locations are documented in Figures 4.4 and 4.5.

4.2 **Zero Referencing**

For each vertical course sequence 2-5, the zero reference point is the center of the upper course girth weld as illustrated in Figure 4.6. The bottom of the wind girder was utilized as the zero reference for Course 1.

Zero referencing for horizontal sequences is illustrated in Figures 4.4 and 4.5.

4.3 **Scan Location Marks**

The extremes of the 12" scan width are stamped and identified with paint. This identification was performed at the scan-start and scan-end. In terms of T-SCAN positioning, the stamp mark pairs denote y-travel from -6.0 to +6.0 inches.

5.0 **Scanner Positioning**

The automatic scanner AWS-5S attaches to the vessel wall by means of magnetic wheels, and scanner travel is directed by microswitches aligned with a magnetic strip. Consequently, placement of the strip is critical to reproducibility. For this application, a chalk line was used to produce a visible reference line for magnetic guide strip placement. In this fashion, the magnetic strip is spaced equidistantly from the inspection area.

5.1 **Scanner Re-Positioning**

In the course of subsequent surveys, it is recommended that the chalk line be equally spaced from the position stamp marks to ensure optimum scan reproducibility.

EXAMINATION INFLUENCES

Paint

The presence of paint will affect the measured thickness of steel by approximately 3 to 4 times the paint thickness. For example, if paint is 0.005" thick, the measured wall thickness is increased by approximately 0.015 to 0.020". In the course of these surveys, variations in paint thickness and smoothness were observed.

Surface Inconsistencies

Examination surface irregularities (eg. grit imbedded in the paint, rolling gouges) were observed in the course of scanning. These influences, while unavoidable, may promote increased thickness measurements in localized areas.

Wind

Fairly strong winds were encountered during scanning. While wind does not affect thickness measurement, it is possible that a small displacement of the 'plumb' chalk line resulted from winds, which would affect scanner positioning with respect to the desired inspection area. The strip displacement did not exceed 1 inch.

Temperature

We observed air temperatures ranging from 25F to 80F. The temperature variations encountered during a scanning day necessitated frequent calibration checks--often exceeding the minimum requirement of procedure. In no case did calibration vary in excess of 0.005 inches from known values.

Girth Welds

Prior to the October scanning, the girth welds were ground flush with the shell material. This enabled, in most cases, thickness measurement over the weld area. It is important to note that the Tank #2 scanning of March, 1989 was performed with reinforcement in the as-welded condition, and thickness measurement adjacent to and over the weld was not possible.

Stairwell

The stairwell obstructed data collection for a portion of some vertical scan sequences. The unscanned length is noted on the data sheet.

Wind Girder

The wind girder obstructed scanning for approximately the first 19 inches of the vertical course 1 scanning sequence.

7.0 DATA REPORTING

7.1 T-SCAN Data (Appendix 1, 2, and 3)

Data from the automated scans is presented in table and hardcopy image form. The tables indicate the maximum, average, and minimum thickness for each scan part. The biased minimum thickness (in millimeter units) used in EVA calculations is noted in the 'comments' column for part :02 of each vertical scan. Additionally, for Tank #2, the measured thickness difference (denoted as 'delta' T) between the March 1989 baseline scanning and the October 1989 examinations is noted adjacent to the Minimum Thickness value. It is suggested that all subsequent scanning sessions be compared to the original T-SCAN baseline data.

Hardcopy T-SCAN images are printed in Course-Sequences whereby thickness values less than the nominal thickness are shown in the TOP view.

7.2 EVA Figures and Tables (Appendix 4)

EVA plots and graphs are included for documentation. Discussion of the significance of EVA calculations is included in Section 10.0

7.3 Radiographic Reproductions (Appendix 5)

Photographic reproductions of the original radiographs are presented in Appendix 5 with a discussion of measurement technique.

8.0 UNDERSTANDING T-SCAN HARDCOPY

The end result of a T-SCAN survey is a permanent record of thickness measurements presented in the form of a T-SCAN image. T-SCAN images (parts) of the scan area may be hardcopied singly or in continuous sequences. T-SCAN images consist of two views of the inspection volume, scaling information, display lines, and color referencing. Figure 8.1 is an example of a T-SCAN printout, and the following image evaluation discussion is based on the figure.

8.1 T-SCAN Image Views

The T-SCAN image of Figure 8.1 is configured to represent two projection planes of the inspection volume. These projection planes are labelled as 'TOP' and 'SIDE'. Each projection plane, or 'view' is bordered by a rectangular frame. By simultaneous use of two projection planes (views), one is able to visualize a three dimensional relief of the inspection volume.

TOP View Frame

The TOP view is as if an observer was viewing the testpiece from above the examination surface. The image length (distance in the x-direction) of the figure is 125 mm. The image width (distance in the y-direction) is 120 mm. Therefore, this image represents a scan area of 125 x 120 mm. Both image length and width may be selected by the operator during a test to minimize inspection time and maximize resolution. The TOP view frame size will not typically vary in dimension for different length/width combinations, and is composed of 15000 thickness data points.

SIDE View Frame

The SIDE view of the figure is a projection view as if an observer was viewing the inspection volume from the side. A projected side view does not represent any single 'slice' of the testpiece, but rather a composite of all side views of the inspection volume projected into one plane. Normally, the top of the SIDE view frame does not represent the outside surface of the testpiece. Hence, SIDE view scaling may be selected to provide increased screen resolution in the thickness dimension. In the figure, the SIDE view frame is a window or expansion of measured thickness where the Upper and Lower display limit is 1.5 and 15.0 mm respectively, as noted to the left of the SIDE view frame.

8.2 T-SCAN Display Level and Color Coding

Display Level: Extending horizontally across the SIDE view is a dotted line denoted as the **Display Level**. The display level may be varied by the operator to investigate thinning trends and locate areas of minimum thicknesses. In the Figure, the display level is set at 14.8 mm. Any portion of the inspection volume which is measured to be less than 14.8 mm is displayed graphically in the TOP view above.

Color Coding: Since T-SCAN images are 'topographic' maps of the inspection volume, colors are used to denote thickness contours or steps. Up to eight colors may be used to visualize the thickness steps. In the Figure, the thickness (color) steps begin at 13.5 mm (BASIS) and continue at thickness intervals to 8.9 mm. Therefore, with a single hardcopy, one may see the extent of corrosion (by use of the display level) and identify the worst-case thinning (by use of the color steps). Thickness 'steps' may be selected by the operator.

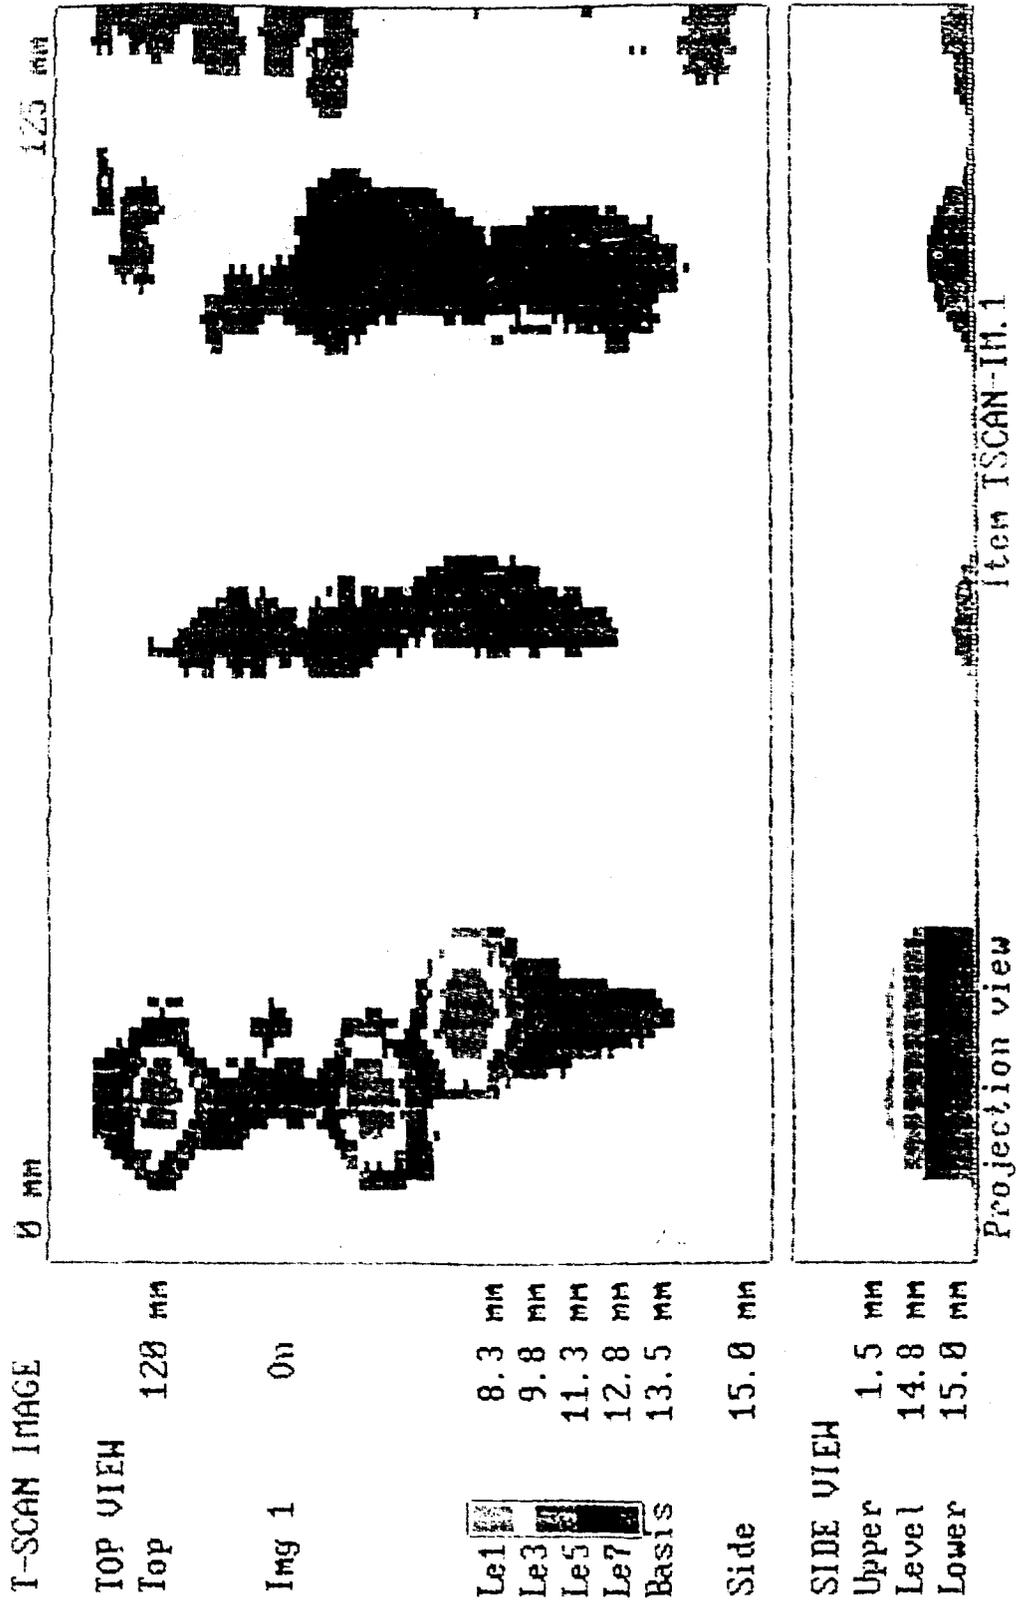

FIGURE 8.1: TYPICAL T-SCAN IMAGE

8.3 Data Dropout

Though the T-SCAN image is an invaluable tool for corrosion and thickness mapping, it must be understood that occasional indications may be superfluous. These inconsistent data may be caused by surface roughness or probe liftoff. Inconsistent data are sometimes called data dropout. T-SCAN procedures describe criteria for dropout acceptance levels which evolved from numerous tests at DNV. Inconsistent data normally may be distinguished by unusual distribution, extreme 'depth', and number of data points involved.

8.4 Additional T-SCAN Hardcopy Options

Though the Figure is a typical hardcopy configuration, the following display features are available when detailed image evaluation is desired:

- Inch/mm conversion
- Per-cent wall loss
- Projected END View
- Sectioned SIDE or END View
- Image Coding (Normally for complex surveys)
- Position Cross Hairs

9.0 APPLICATION OF EVA TO BASIN F STORAGE TANK SURVEYS

9.1 EVA Overview

Extreme Value Analysis (EVA) is a statistical sampling technique frequently used on storage tank bottoms to predict the minimum remaining thickness based on data collected with the P-SCAN instrument. In conventional examinations, the EVA surveys are performed as follows:

- Determine the optimum number of survey locations to be surface prepared. DNV specifies this number based on tank diameter and statistical requirements.
- Surface prepare the required number of survey locations by needle gun/wire brushing or light sandblasting.
- Perform T-SCAN thickness mapping of each location
- Analyze T-SCAN data files to determine minimum thickness for each survey location.
- Input the minimum thickness values into the Extreme Value Analysis program and produce curves for three methods of analysis.

9.2 Modification of EVA to Basin F Tank Surveys

EVA procedures and analysis software currently approach predictions of wall loss by means of extreme minimum thicknesses for each sample area. The presumption made is that factors promoting corrosive wall loss result in a consistent pitting distribution. In the case of the Basin F Storage tanks, the nominal wall thickness is not a constant for all courses; the lower courses are thicker. Consequently, in order to apply the EVA concepts, the following considerations were given for Part :02 of each vertical course-sequence:

- Minimum and average thickness for Courses 1, 2, and 3 were converted to millimeters.
- The arithmetic mean of all tabulated average thicknesses (for courses 1, 2, and 3) was calculated. For these surveys, the calculated mean was found to be:

TANK #1:	0.778 " (19.8 mm)
TANK #2:	0.778 " (19.8 mm)
TANK #3:	0.785 " (19.9 mm)
- For data of courses 4 and 5, it was necessary to bias the thickness to represent the thickness of Courses 1, 2, and 3. Therefore, for Course 4 and 5 part :02 data, the difference between the tabulated average thickness and the tabulated minimum thickness was subtracted from the arithmetic mean calculated above.
- EVA calculations are performed on the biased data, and the minimum predicted thickness is presented by the EVA program. This minimum thickness is then subtracted from the mean thickness to provide the maximum predicted wall loss.

9.3 Understanding EVA Plots (Appendix 1)

A full understanding of EVA plots may be accomplished only with complete knowledge of Extreme Value Statistics. For those unfamiliar with Extremal Statistics, general attributes of the EVA plots are noted below:

- Plot Title: Appears at the top of the plot and is generally used to identify the tank number and client.

- EVA Frame: Appears at the upper right of the plot with a number of analysis parameters:
 - METH Identifies the algorithm method used to produce the plot. Currently, three methods are available for use.
 - DATE: Date of EVA Survey
 - RTN: Numerical value of the Return Period, a parameter used to derive the predicted minimum thickness for the METHOD. For all tanks, the return period was calculated to be 7897.
 - DEVY: For least squares linear regression, this denotes the Standard Deviation in the thickness dimension.
 - CORR: Denotes the correlation coefficient of the total sample variate for the METHOD in current use. A 'good' correlation is considered to be between -0.95 and -1.0 and data points will closely approximate the regression line.

- Plot Scaling: Four scales are incorporated in the EVA plots
 - 1 Remaining Thickness: Directly related to the minimas derived from the original T-SCAN tabulated data.
 - 2/3 Standard Extremal Variate and Probability
Two mathematically related scales used in statistical evaluation after data reduction and transformation.
 - 4 Return Period (Not shown) A horizontal scale mathematically related to Standard Extremal Variate and Probability scales and is used in defining the minimum predicted thickness for the METHOD in current use.

- Data Points: All unique minima values are assigned a corresponding Standard Extremal Variate and are plotted as points or squares, depending on the METHOD in current use. A best fit regression line is calculated and extrapolated to intersect with the appropriate return period. The corresponding minimum thickness for the METHOD is printed adjacent to the line.

10.0 DISCUSSION

10.1 Comparison of T-SCAN Data with DNV-QAS Preservice Baseline

A comparison of the minimum measured thickness of the automated surveys and the pre-service grid measurements was made and the following table summarizes the results. It must be emphasized that the pre-service grid measurements were obtained after removing localized areas of paint. Hence, the grid measurements are without paint influence. Conversely, T-SCAN measurements were influenced by paint.

TANK NO.	QAS-Loc.	T-SCAN Image	DNV-QAS Data		T-SCAN Data

10.2 Isolated Thin Areas

During evaluation of the data, several small isolated areas of thinning were noted. While it is possible that the thinning was the result of corrosion, it is likely that some of the 'pit' measurements were actually surface gouges or 'pock-marks' that existed at fabrication. A casual visual examination of the outside surface noted scattered areas of gouges (presumably from rolling) and small depressions. It is assumed that similar anomalies exist internally. External grinding was noted where alignment lugs were once welded during construction. Since the inside surface of the wall was smoothed by grinding and sandblasting, it is probable that shallow depressions remained after surface preparation. Indeed, adjacent to some girth welds, reduced thickness (by 0.010 to 0.060") was measured.

10.3 Tank #2 Wall Profile Changes

Following data evaluation and application of EVA, it was found that a general wall loss of approximately 0.015" has occurred since March 1989. However, a deviation of the general wall loss observation was identified in Scan 6, Course 5, Part 4 (File TK2-S6C5.4).

In March 1989, the minimum thickness for Image TK2-S6C5.4 was found to be 0.915". The October 1989 minimum measurement for the same area was 0.825". These data indicate a localized wall loss of approximately 0.090"/6 months. Concurrent with the wall loss was a band of reduced measurements just above the floor level as evidenced by horizontal scans TK2-H3C5 and TK2-H4C5. This band, which was not as pronounced in March 1989, currently extends for approximately 10 feet about the circumference.

10.0 DISCUSSION

10.1 Comparison of T-SCAN Data with DNV-QAS Preservice Baseline

A comparison of the minimum measured thickness of the automated surveys and the pre-service grid measurements was made and the following table summarizes the results. It must be emphasized that the pre-service grid measurements were obtained after removing localized areas of paint. Hence, the grid measurements are without paint influence. Conversely, T-SCAN measurements were influenced by paint.

TANK NO.	QAS-Loc.	T-SCAN Image	DNV-QAS Data		T-SCAN Data	
			Min T.	Avg T.	Min T.	Avg T.
1	09	TK1-S3C4.4	0.850	0.862	0.850	0.885
1	05	TK1-S1C4.1	0.822	0.837	0.820	0.855
1	08	TK1-S5C4.4	0.833	0.838	0.815	0.855
1	07	TK1-S7C4.4	0.845	0.850	0.850	0.870

10.2 Isolated Thin Areas

During evaluation of the data, several small isolated areas of thinning were noted. While it is possible that the thinning was the result of corrosion, it is likely that some of the 'pit' measurements were actually surface gouges or 'pock-marks' that existed at fabrication. A casual visual examination of the outside surface noted scattered areas of gouges (presumably from rolling) and small depressions. It is assumed that similar anomalies exist internally. External grinding was noted where alignment lugs were once welded during construction. Since the inside surface of the wall was smoothed by grinding and sandblasting, it is probable that shallow depressions remained after surface preparation. Indeed, adjacent to some girth welds, reduced thickness (by 0.010 to 0.060") was measured.

10.3 Tank #2 Wall Profile Changes

Following data evaluation and application of EVA, it was found that a general wall loss of approximately 0.015" has occurred since March 1989. However, a deviation of the general wall loss observation was identified in Scan 6, Course 5, Part 4 (File TK2-S6C5.4).

In March 1989, the minimum thickness for Image TK2-S6C5.4 was found to be 0.915". The October 1989 minimum measurement for the same area was 0.825". These data indicate a localized wall loss of approximately 0.090"/6 months. Concurrent with the wall loss was a band of reduced measurements just above the floor level as evidenced by horizontal scans TK2-H3C5 and TK2-H4C5. This band, which was not as pronounced in March 1989, currently extends for approximately 10 feet about the circumference.

10.4 EVA Results

The maximum predicted pit depth for the tanks was calculated to be:

TANK 1:	0.085" \pm 0.020"
TANK 2:	0.126" \pm 0.020"
TANK 3:	0.099" \pm 0.015"

It is clear that Tank #2 has a general thickness distribution slightly less than Tanks 1 and 3. The comparatively small predicted wall loss of Tank 1 and Tank 3 is likely to be the result of plate nominal thickness variations and slight corrosion arising from condensation.

10.4.1 EVA Predictions and Tank #2 Measurements

Measured Wall Loss

The most significant reduction of wall thickness was found to be at the bottom of Scan 6, Course 5. The current (October 1989) minimum thickness of this scan area was found to be 0.825 inches. The average thickness of the steel plate in which the thinning occurred was measured in the pre-service baseline as 0.952 inches. Hence, the approximate wall loss may be found:

$$0.952 - 0.825 = 0.127 \text{ inches.}$$

Predicted Wall Loss

The EVA calculations based on the data of October 1989 predict a maximum pit depth of 0.126 inches. This prediction is based only on part :02 data. The thinning detected in part :04 with a minimum measurement of 0.825" played no role in the EVA calculations. Hence, it is important to note that even if the thinning was not detected, the depth of pitting would have been predicted. The wall loss observed in Scan 6, Course 5 is, at this time, consistent with the pitting distribution model assumed in EVA calculations. It appears to be coincidence that the scan areas of the corrosion monitoring program include the 'worst-case' thinning.

10.5 Radiographic Observations

The minimum valve stem thickness, as determined by radiographic methods were found to be:

TANK 1:	0.530"
TANK 2:	0.530"
TANK 3:	0.525"

Slight corrosion was noted in V-7 and V-8 of Tank #2. Evidence of sediment or other substance build-up was observed with all tanks. A machine screw was detected in Tank #1, Valve #5.

APPENDIX 5: RADIOGRAPHIC FILM REPRODUCTIONS AND RESULTS

Each 1.5" diameter valve V-1 through V-8 was subjected to two radiographic examinations. Exposures were taken vertically (0 Degree) and horizontally (90 Degrees) to detect wall loss and build-up of material. Minimum thicknesses for each valve were determined by means of a comparator. Thickness measurements by radiographic methods are considered to be accurate to within ± 0.020 ". The results of the radiographic film interpretation are summarized below:

<u>TANK NUMBER</u>	<u>VALVE NUMBER</u>	<u>MINIMUM THICKNESS</u>	<u>COMMENT</u>
1	V-1	0.540 "	
	V-2	0.535 "	
	V-3	0.535 "	
	V-4	0.535 "	Build-up
	V-5	0.547 "	Screw inside
	V-6	0.530 "	Build-up
	V-7	0.530 "	
	V-8	0.530 "	
2	V-1	0.530 "	
	V-2	0.530 "	
	V-3	0.530 "	
	V-4	0.530 "	
	V-5	0.530 "	Build-up
	V-6	0.540 "	
	V-7	0.535 "	Corrosion
	V-8	0.530 "	Corrosion
3	V-1	0.525 "	
	V-2	0.530 "	
	V-3	0.530 "	
	V-4	0.535 "	Build-up
	V-5	0.530 "	
	V-6	0.540 "	Build-up
	V-7	0.530 "	
	V-8	0.530 "	Build-up

The radiographic examination was conducted by MQS Inspection, Inc for DNV Industrial Services. DNV personnel supervised the inspections and assisted the MQS radiographer in obtaining exposures. The original MQS report is included for additional documentation.

The Radiographic Reproductions

All radiographs obtained during the inspections are reproduced and labelled. However, it is important to note that while every effort was made to retain the film detail, slight variations of film density resulted in occasional unsharpness in the reproduced prints. Additionally, it was not possible to reproduce the lead letters of the film identification without bleaching the valve image; hence, the identification is overlaid. Each page of reproductions includes the vertical and horizontal exposure for the valve.
